Shape Control of Deformable Linear Objects with Offline and Online Learning of Local Linear Deformation Models

Mingrui Yu, Hanzhong Zhong, and Xiang Li

Abstract—Shape control of deformable linear objects (DLOs) is challenging, since it is hard to obtain the deformation models. Previous studies often approximate the models in purely offline or online ways. This abstract proposes a scheme for shape control of DLOs, where the unknown model is estimated with both offline and online learning, allowing for both accurate modeling via offline learning and further updating for new DLOs via online learning. The simulation and real-world experiments show that the proposed method can achieve DLO shape control better than previous works.

I. INTRODUCTION

Deformable linear objects (DLOs) refer to deformable objects in one dimension [1]. In the field of DLO shape control, a key challenge is to obtain the exact models of DLOs, because they are hard to calculate theoretically and vary among DLOs [2]. Some analytical modeling methods can be used to model DLOs [3]–[5]. However, all are approximate models, and require accurate parameters of DLOs which are difficult to acquire. Data-driven approaches have been applied to learn the deformation models. A common method is to first offline learn a forward kinematics model (FKM) offline, and then use model predictive control (MPC) in manipulation [6]–[9]. Reinforcement learning and imitation learning methods have also been studied [10]–[13]. The problem is that they are less data-efficient and may get into trouble manipulating an untrained DLO. Apart from these offline approaches, some studies have used purely online methods to estimate the local linear deformation model of manipulated DLOs, which can be applied to any new DLO [14]–[17]. However, these online estimated models are less accurate because only limited local data can be utilized.

In this abstract, we propose a scheme for shape control of DLOs, where the unknown deformation model is estimated with both offline and online learning, shown in Fig. 1. Specifically, we use a radial-basis-function neural network (RBFN) to model the mapping from the state to the local linear deformation model. In the offline phase, the RBFN is trained on random data. The offline model is then seamlessly migrated to the online phase as an initial estimation. In the online phase, an adaptive controller is proposed to control the shape, in which the RBFN is further updated to adapt to the manipulated DLO concurrently. Thus, the offline learning and online learning complement each other. The system’s stability is analyzed using the Lyapunov method. Simulation and real-world experiment results are presented to demonstrate the better performance of the proposed scheme compared with the previous methods. The full paper [18], video, and code are available at the project website1. A further improved work can be found here2.

II. METHODOLOGY

This abstract considers quasi-static shape control of elastic DLOs, as illustrated in Fig. 1. Some frequently-used notations are listed as follows. The vertical concatenation of column vector $a$ and $b$ is denoted as $[a; b]$. The position vector of the end-effectors is represented as $r \in \mathbb{R}^n$. The position of the $i$th feature is represented as $x_i \in \mathbb{R}$. The overall shape vector of the DLO is represented as $x = [x_1; \cdots; x_m] \in \mathbb{R}^{lm}$, where $m$ is the number of the features.

A. Local Linear Deformation Model

The velocity vector of the DLO features can be locally linearly related to the velocity vector of the end-effectors using a Jacobian matrix [14]–[17]. Different from the previous works, we estimate the Jacobian matrix by learning the mapping from the state $(x, r)$ to the Jacobian matrix $J$:

$$\dot{x} = J(x, r)\dot{r}$$

(1)

Proposition: With the quasi-static assumption, the velocity vector of the features on the elastic DLO can be related to the velocity vector of the end-effectors as (1).

Proof: Denote the potential energy of the elastic DLO as $E$, which is assumed to be fully determined by $x$ and $r$. In the quasi-static assumption, internal equilibrium holds at all states during the manipulation. That is, $\partial E/\partial x = 0$ at any state. Consider the DLO is moved from state $(\bar{x}, \bar{r})$ to state $(\bar{x} + \delta x, \bar{r} + \delta r)$ where $\delta x$ and $\delta r$ are small displacements of the features and the end-effectors. Denote $\partial E/\partial x$ as $g(x, r)$.

1https://mingrui-yu.github.io/shape_control_DLO/
2https://mingrui-yu.github.io/shape_control_DLO_2/
\[ \frac{\partial^2 E}{\partial x \partial x} \] as \( A(x, r) \), and \( \frac{\partial^2 E}{\partial x \partial r} \) as \( B(x, r) \).

Using Taylor expansion and neglecting higher order terms:

\[ g(x + \delta x, r + \delta r) \approx g(x, r) + A(x, r) \delta x + B(x, r) \delta r \] (2)

where \( g(x + \delta x, r + \delta r) = g(x, r) \) = 0. Assuming the DLO has a positive and full-rank stiffness matrix around the equilibrium point, matrix \( A \) is invertible [14]. Then, we have

\[ \delta x \approx -(A(x, r))^{-1} B(x, r) \delta r \] (3)

In slow manipulations, \( \dot{x} \approx \delta x / \delta t \) and \( \dot{r} \approx \delta r / \delta t \) with small \( \delta t \). Then, denoting \( -(A(x, r))^{-1} B(x, r) \) as \( J(x, r) \), we derive (1) and prove the proposition.

Note that (1) can be rewritten as

\[ \dot{x} = \begin{bmatrix} \dot{x}_1 \\ \vdots \\ \dot{x}_m \end{bmatrix} = \begin{bmatrix} J_1(x, r) \\ \vdots \\ J_m(x, r) \end{bmatrix} \dot{r} \] (4)

where \( J_k(x, r) \) is the \((k-1)l + 1\)th to \((kl)\)th rows of \( J(x, r) \). Thus, it can be obtained that

\[ \dot{x}_k = J_k(x, r) \dot{r}, \quad k = 1, \cdots, m \] (5)

which indicates that different features correspond to different Jacobian matrices.

**B. Offline Learning**

We apply a neural network (NN) to approximate the Jacobian matrix, in which the input is the current state and the output is the Jacobian. Two properties of the Jacobian can be noticed intuitively: 1) translation-invariance: translation of the whole DLO will not alter the Jacobian matrix; 2) approximate scale-invariance: DLOs with different lengths but similar overall shapes may have similar Jacobian matrices. Thus, to improve the NN’s generalization ability, we modify the representation of the input state from \([x; r]\) to

\[ \phi \triangleq [\bar{x}_1; \cdots; \bar{x}_m; \bar{p} ; q_0 ; q_1] \] (6)

where

\[ \bar{x}_k = \frac{\begin{bmatrix} x_k - p_0 \\ x_k - p_1 \end{bmatrix}}{\|x_k - p_0\| \|x_k - p_1\|}, \quad \bar{p} = \frac{p_1 - p_0}{\|p_1 - p_0\|} \] (7)

\((k = 1, \cdots, m)\), where \(p_0, p_1\) are the positions of the left and right grasped ends of the DLO, and \(q_0, q_1\) are the orientations of the left and right grasped ends.

Then, (5) can be rewritten as

\[ \dot{x}_k = J_k(\phi) \dot{r}, \quad k = 1, \cdots, m \] (8)

We apply a radial-basis-function network (RBFN) [19] to represent the actual Jacobian matrix as a function of \( \phi \):

\[ \text{vec}(J_k(\phi)) = W_k \theta(\phi), \quad k = 1, \cdots, m \] (9)

where \( \text{vec}(\cdot) \) refers to the column vectorization operator, and \( W_k \) is unknown actual RBFN weights for the \(k\)th feature. The \( \theta(\phi) \) represents the vector of activation functions. We use the gaussian radial function as the activation function. Equation (9) can be decomposed as

\[ J_{ki}(\phi) = W_{ki} \theta(\phi), \quad i = 1, \cdots, n \] (10)

where \( J_{ki} \) is the \(i\)th column of \( J_k \), and \( W_{ki} \) is the \((i-1)l + 1\)th to \((il)\)th rows of \( W_k \). Substituting (10) into (8) yields

\[ \dot{x}_k = J_k(\phi) \dot{r} = \sum_{i=1}^{n} J_{ki}(\phi) \dot{r}_i = \sum_{i=1}^{n} W_{ki} \theta(\phi) \dot{r}_i \] (11)

where \( \dot{r}_i \) is the \(i\)th element of \( \dot{r} \). The estimated Jacobian matrix is represented as

\[ \text{vec}(\hat{J}_k(\phi)) = \hat{W}_k \theta(\phi) \] (12)

where \( \hat{W} \) is estimated weights. The architecture of the RBFN is shown in Fig. 2. The approximation error for the \(k\)th feature \( e_k \) is specified as

\[ e_k = \dot{x}_k - \hat{J}_k(\phi) \dot{r} = \sum_{i=1}^{n} W_{ki} \theta(\phi) \dot{r}_i - \sum_{i=1}^{n} \hat{W}_{ki} \theta(\phi) \dot{r}_i = \sum_{i=1}^{n} \Delta W_{ki} \theta(\phi) \dot{r}_i \] (13)

We use the smooth L1 loss [20] of \( e_k \) for offline training.

**C. Adaptive Control through Online Learning**

We propose an adaptive control scheme, in which the offline estimated model is treated as an initial approximation and then further updated during the shape control tasks. The target points can be any subset of the features, whose indexes form set \( \mathcal{C} \). Then, the target shape vector \( x^c \) and target Jacobian matrix \( J^c(\phi) \) are denoted as \( x^c = [\cdots x_k; \cdots] \), \( J^c(\phi) = [\cdots; J_k(\phi); \cdots] \), \( k \in \mathcal{C} \). The velocity vector of the robot end-effectors \( \dot{r} \) is controlled and specified as

\[ \dot{r} = -\alpha \left( J^c(\phi) \right)^\dagger \Delta x^c \] (14)

where \( \left( J^c(\phi) \right)^\dagger \) is the Moore-Penrose pseudo-inverse of the estimated Jacobian matrix. In addition, \( \Delta x^c = x^c - x^c_{\text{desired}} \) where \( x^c_{\text{desired}} \) is the desired position vector of the target points, and \( \alpha \in \mathbb{R} \) is a positive control gain.

The online updating law of the \(j\)th row of \( \hat{W}_{ki} \) of the RBFN is specified as

\[ \hat{W}_{kij} = \dot{r}_i \theta(\phi)(\eta_1 \Delta x_{kj} + \eta_2 e_{kj}), \quad j = 1, \cdots, l \] (15)

where \( \Delta x_{kj} \) is the \(j\)th element of the task error \( \Delta x_k \), and \( e_{kj} \) is the \(j\)th element of the approximation error \( e_k \). The \( \eta_1 \) and \( \eta_2 \) are positive scalars. Such updating is done for all \( k \in \mathcal{C} \) and \( i = 1, \cdots, n \).

Fig. 3. Some of the shape control tasks accomplished using our method in real-world experiments. The left end of the DLO is grasped by a UR5 arm and the right end is fixed. The green+black circles represent the desired positions of the DLO features. In all cases, the DLO starts from a straight line.

Fig. 4. The simulation environment. The blue points represent the features along the DLO. The green points represent the desired positions of the features.

Fig. 5. The relationship between the offline modeling accuracy and the amount of training data.

III. RESULTS

We carry out both simulation and real-world experiments to validate the proposed method. The simulation environment is shown in Fig. 4. We choose three representative classes of methods for comparison: 1) learning FKM offline and using MPC for shape control (FKM+MPC); 2) estimating the Jacobian matrix online using weighted least square estimation (WLS); 3) reinforcement learning (SAC).

A. Offline Learning of the Deformation Model

We test the offline modeling accuracy on a certain DLO and its relationship to the amount of training data, in which we compare our local linear Jacobian model with nonlinear forward kinematics models based on multi-layer perceptrons (MLP) or biLSTM. The data are randomly collected in the simulation. As shown in Fig. 5, the results indicate that our Jacobian model can achieve higher prediction accuracy with less training data.

B. Shape Control with Online Learning

We evaluate the proposed control method and compare it with other methods. If the final task error is less than 5cm, the task is regarded successful. The average task error refers to the average task error of only the successful cases.

1) Simulation: First, we test their performance in both 2D and 3D DLO shape control tasks in simulation. The manipulated DLO is a new DLO not used in the offline learning, and 100 cases with different feasible desired shapes are tested. As shown in Table I, our method significantly outperforms the compared methods on both success rate and average task error, even using much less offline training data.

2) Real-world experiments: We also evaluate these methods in real-world 2D tasks, as shown in Fig. 3. The same offline models as those in the simulation are used (no real-world data are collected offline). We separately carry out 5 tests with different feasible desired shapes on two different DLOs. The results are shown in Table II. Our method completes all 10 tasks and achieves the lowest average task error, where the online learning enables faster and more precise control.

IV. CONCLUSION

This abstract considers the shape control of DLOs with unknown deformation models. First, the offline learning well initiates the estimation of the model. Then, the adaptive control scheme with online learning further updates the model and achieves shape control. The experiments demonstrate the effectiveness of our method.
